

*This is Micro-Container Architecture Based*  
**DOCKER PROJECT**

---

Rakesh Kumar Jangid  
Date: 20-06-2023

## □ **INTRODUCTION**

- ★ We are embarking on a project to create a Decoupled Microservice-based system using Docker containers. This project involves several key components and resources that we will need to set up. Here's an overview of what we'll be working on:
- ★ **Computing Resources:** We will require sufficient computing resources, such as servers or virtual machines, to host our Docker containers. These resources should have enough processing power, memory, and storage capacity to handle the workload of our microservices.
- ★ **Load Balancers:** To distribute incoming network traffic across multiple containers and ensure high availability and scalability, we will incorporate load balancers into our system. Load balancers help evenly distribute requests and optimise the utilization of resources.
- ★ **External Volume Storage:** For persistent data storage, we'll need to set up external volume storage. This allows our containers to store and retrieve data even if they are restarted or moved between different hosts. We'll configure Docker volumes or use external storage solutions like network-attached storage (NAS) or cloud-based storage services.
- ★ **MySQL:** As a critical component of many web applications, we'll include a MySQL database in our system. This will provide a reliable and scalable solution for storing and managing our application's data. We'll set up a MySQL container and configure it to ensure proper data persistence and security.
- ★ **WordPress Images for Containers:** If our project involves hosting WordPress websites, we'll need Docker images specifically built for WordPress. These images contain all the necessary dependencies and configurations to run WordPress within a containerized environment.
- ★ **Configuration and Settings:** Throughout the project, we'll need to define various configurations and settings for our microservices, load balancers, storage, and database. These configurations will include network settings, environment variables, security parameters, and other relevant parameters required for proper operation.

- ★ Pre-System Setup: Before we can start building our project, we may need to perform some pre-system setup tasks. This could involve installing and configuring Docker on our computing resources, setting up the networking environment, ensuring firewall rules allow necessary communication, and other prerequisites.
  - ★ We will proceed with this project by following a step-by-step approach. Each step will involve specific tasks, such as setting up computing resources, configuring load balancers, creating Docker volumes, deploying MySQL and WordPress containers, and managing configurations. By completing each step, we'll gradually build our decoupled microservice-based system using Docker containers.
- 

## ☐ **CREATE CLOUD INFRASTRUCTURE RESOURCES INCLUDING :- EC2 INSTANCES, EFS VOLUME, ELASTIC-IP, NLB**

### **❖ PRE- SYSTEM CONFIGURATION**

Name	Configuration & Setup
Docker-Server1 & Docker-Server2	edit hosts file with all connected instances ip setup repository on /etc/yum.repos.d/online.repo setup EPEL repository (if system os is fedora based) set hostname

### **❖ Mount EFS volumes between Docker-Server1 and Docker-Server2 EC2 instances :-**

Filter by property values

	Name	File system ID	Encrypted	Total size	Size in Standard / One Zone	Size in Standard-IA / One Zone-IA	Provisioned Throughput (MiB/s)
	Docker_Server_EFS_Volume	fs-0b0f1a581bad7027a	Unencrypted	808.74 MiB	808.74 MiB	0 Bytes	-

```
# mkdir -p /mnt/efs
# yum install nfs-utils
# systemctl enable nfs-client.target
# systemctl is-enabled nfs-client.target
# mount -t nfs4 -o nfsvers=4.1,rsize=1048576,wsiz=1048576,hard,timeo=600,retrans=2,
  noresvport 172.31.31.202:/ /mnt/efs
# vi /etc/fstab
172.31.31.202:/ /mnt/efs nfs4 nfsvers=4.1,rsize=1048576,wsiz=1048576,hard,timeo=600,
  retrans=2,noresvport
# mount -a
# df -hT
# mount | grep /mnt/efs
```

-----Note:- Ping both server instances and make ssh connection with passwordless login-----

The screenshot shows a terminal window titled "Docker-Server 1". The menu bar includes Terminal, Sessions, View, X server, Tools, Games, Settings, Macros, and Help. Below the menu is a toolbar with icons for file explorer, terminal, game controller, star, monitor, and help. A "Quick connect..." search bar is present. The terminal content displays file system details for three partitions:

UUID	Mount Point	File System	Options	Size	Used
UID=287d9c0b-0e0f-4e92-8534-45733aa3dc68	/	xfs	defaults	0	0
UID=7bc24af7-289d-4bce-b17e-300c3aafe968	/boot	xfs	defaults	0	0
UID=7B77-95E7	/boot/efi	vfat	defaults,uid=0,gid=0,umask=077,shortname=winnt	0	2

Below this, a network configuration line is shown: `172.31.31.202:/ /mnt/efs nfs4 nfsvers=4.1,rsz=1048576,wsz=1048576,hard,timeo=600,retrans=2,noresvport 0 0`. The left sidebar shows "Sessions" and "Tools" tabs.

## ❖ Work on Docker-Server1 & 2

### ➤ Docker Setup on EC2-Instances

```
# yum -y install git
# git --version
#-----> For fedora & Debian Based Linux Version:-
# git clone https://github.com/rakesh08061994/docker.git
# cd docker
# chmod a+x Docker_Setup_On_Debian.sh
# chmod a+x Docker_Setup_on_fedora.sh
# ./Docker_Setup_on_fedora.sh
# ./Docker_Setup_On_Debian.sh
# systemctl restart docker
# systemctl enable docker
```

```
# systemctl is-enabled docker
# docker info
# docker --version
```

## ➤ Create Network Bridge for application isolation (Server1 & 2)

```
# docker network ls
# docker network create --help
# docker network create amazon --driver=bridge --subnet=192.168.0.0/24 --gateway=192.168.0.1
# docker network create azure --driver=bridge --subnet=182.168.0.0/24 --gateway=182.168.0.1
# docker network ls
# docker network inspect amazon
# docker network inspect azure
```

Quick connect...

2. Docker-Server 1

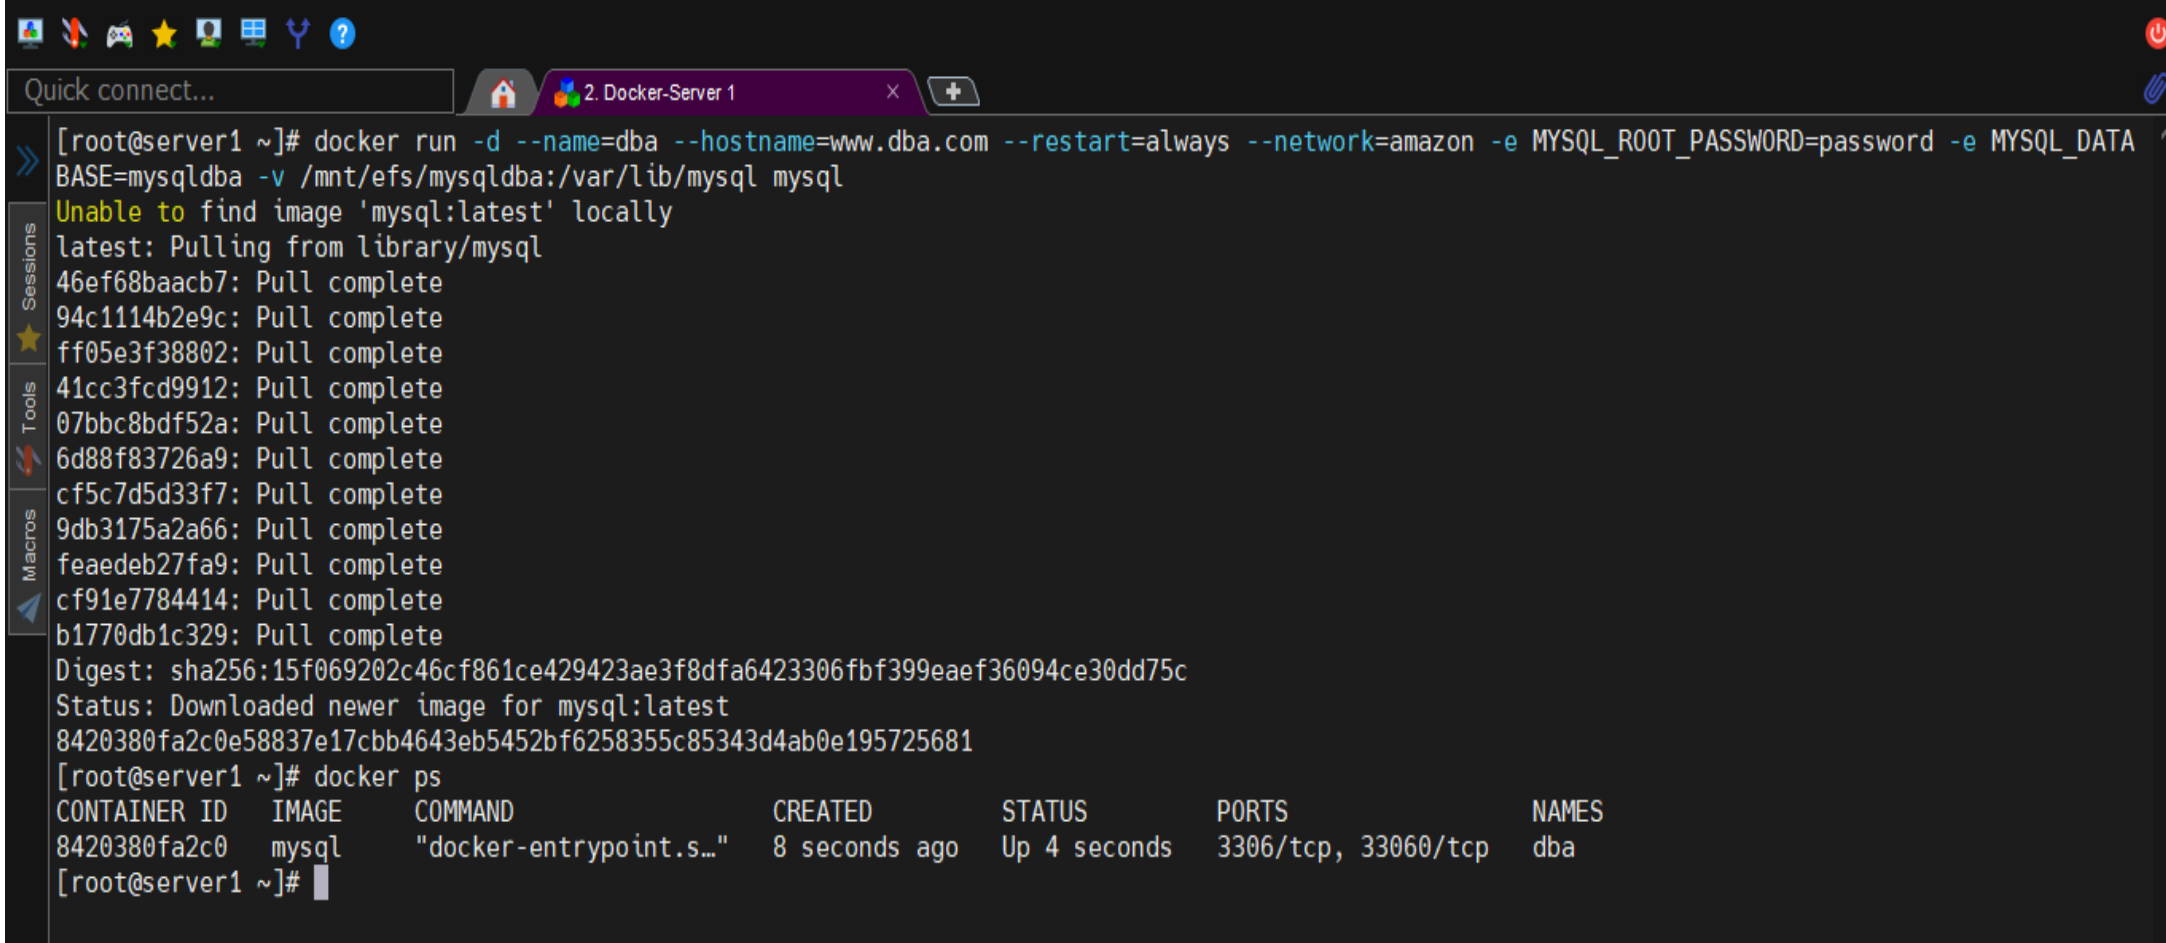

```
[root@server1 ~]# docker network create amazon --driver=bridge --subnet=192.168.0.0/24 --gateway=192.168.0.1
a3fa81af93e3573cc7b3d33dc72862915950c427ea4fb34d09a73e1618556354
[root@server1 ~]# docker network create azure --driver=bridge --subnet=182.168.0.0/24 --gateway=182.168.0.1
c63ad8007d24c277e72a6e20ae8c2aad1eca41ffa363bd40abd1688061b1d295
[root@server1 ~]# docker network ls
NETWORK ID          NAME        DRIVER    SCOPE
a3fa81af93e3        amazon     bridge    local
c63ad8007d24        azure     bridge    local
2a35405385aa        bridge    bridge    local
d3c58ee0d851        host      host      local
325e91825645        none      null      local
[root@server1 ~]#
```

## ➤ Create MYSQL Database Container (Server1 & 2)

```
# docker run -d --name=dba --hostname=www.dba.com --restart=always --network=amazon -e
  MYSQL_ROOT_PASSWORD=password -e MYSQL_DATABASE=mysqlldb -v
  /mnt/efs/mysqlldb1:/var/lib/mysql mysql

docker run -d --name=dba --hostname=www.dba.com --restart=always --network=amazon -e
  MYSQL_ROOT_PASSWORD=password -e MYSQL_DATABASE=mysqlldb -v
  /mnt/efs/mysqlldb2:/var/lib/mysql mysql
```

The screenshot shows a terminal window with a dark background. At the top, there's a taskbar with various icons and a window title bar that says "2. Docker-Server 1". The terminal content shows a series of Docker commands and their output. The first command is to run a MySQL container with specific settings. The output indicates that the 'mysql:latest' image was not found locally and was pulled from the library. The pull progress is shown with a list of layers being pulled. After the pull is complete, the container is started. The final output shows the container's status as 'Up 4 seconds' and its name as 'dba'.

```
[root@server1 ~]# docker run -d --name=dba --hostname=www.dba.com --restart=always --network=amazon -e MYSQL_ROOT_PASSWORD=password -e MYSQL_DATA
BASE=mysqlldb -v /mnt/efs/mysqlldb:/var/lib/mysql mysql
Unable to find image 'mysql:latest' locally

## ➤ SYNCHRONISATION REAL TIME MYSQL DATABASE BETWEEN TWO SYSTEMS.

To achieve real-time synchronization of MySQL and WordPress data between two systems, you can consider implementing database replication with the following steps:

- ❖ Configure MySQL replication: MySQL provides built-in replication features that allow you to replicate data between multiple database servers. You'll need to set up one server as the master and the other as the replica.
  - a. On the master machine, enable binary logging in the MySQL configuration file (my.cnf) by adding the `log_bin = mysql-bin` line.
- ❖ b. Create a replication user on the master machine with appropriate permissions for replication.
- c. On the replica machine, configure the MySQL replication settings by editing the my.cnf file. Set the replica's unique server ID and configure the replication connection details, such as the master host, user, and password.
- d. Start the MySQL replication process on the replica machine, connecting it to the master server. The replica will start syncing data from the master in real-time.

- ❖ Update WordPress configuration: In the WordPress installation on both machines, you'll need to update the wp-config.php file to use the appropriate database connection settings for each server.
  - a. Locate the wp-config.php file in the WordPress installation directory.
  - b. Update the database connection details (host, database name, username, password) to match the respective MySQL server on each machine.
- ❖ Configure the EFS for file synchronization: Since you have already mounted an EFS on both machines, you can use it to synchronize the WordPress files between the two systems.
  - a. Ensure that the WordPress files and directories are stored on the EFS mount point.
  - b. Modify the wp-config.php file on both machines to use the EFS path for the WP\_CONTENT\_DIR and WP\_CONTENT\_URL constants.
  - c. This setup will ensure that both instances share the same WordPress files stored on the EFS, allowing changes made on one system to be immediately reflected on the other.
- ❖ With these steps, you will have MySQL database replication set up between the two machines, ensuring real-time synchronization of data. Additionally, the shared EFS will enable both systems to use the same WordPress files, eliminating discrepancies between the instances.
- ❖ Remember to thoroughly test the setup and ensure that both machines are properly configured before deploying it to a production environment.

Certainly! Here's a step-by-step guide to implementing real-time synchronization of MySQL and WordPress data between two machines using database replication and an EFS:

#### Prerequisites:

- Two EC2 instances (Machine A and Machine B) with WordPress and MySQL installed.
- An EFS file system mounted on both machines.

To synchronize the MySQL databases and WordPress data between two Linux servers for running two web applications, you can follow the detailed steps outlined below:

Set up the target server: Ensure that the target server has a web server (such as Apache or Nginx) installed, along with PHP and MySQL. Install WordPress on the target server but do not configure it yet. Configure the source server: Make sure that the source

server is properly configured and running the WordPress site with the desired data. Verify that the source server has a working MySQL database containing the necessary tables and records. Install and configure MySQL replication: MySQL replication is a mechanism that allows you to synchronize data between two servers. Set up MySQL replication between the source and target servers by following these steps:

a. On the source server, open the MySQL configuration file (**my.cnf or my.ini**) and enable the replication settings by adding the following lines:

```
# docker ps
# docker cp dba:/etc/my.cnf .
# vi my.cnf
[mysqld]
server-id = 1
log_bin = /var/log/mysql/mysql-bin.log
binlog_do_db = mysqldb
```

b. Restart the MySQL service on the source server for the changes to take effect.

Log in to the MySQL shell and create a replication user with the necessary privileges. Replace <replication\_user> and <password> with your desired values:

```
# docker exec -it dba /bin/bash
bash-4.4# mysql -u root -p
Password
mysql> CREATE USER 'repl'@'%' IDENTIFIED BY 'password';
mysql> GRANT REPLICATION SLAVE ON *.* TO 'repl'@'%';
```

```
mysql> FLUSH PRIVILEGES;
```

In the MySQL shell, run the following command and note down the values of Master\_Log\_File and Exec\_Master\_Log\_Pos:

```
mysql> SHOW MASTER STATUS;
```

c. On the target server, open the MySQL configuration file and add the following lines:

```
server-id = 2  
replicate-do-db = mysqldb  
# docker cp ./my.cnf dba:/etc/my.cnf
```

Restart the MySQL service to apply the changes.

Log in to the MySQL shell and run the following command, replacing the placeholders with the values from the master server:

(On server2)

```
# docker exec -it dba /bin/bash  
bash-4.4# mysql -u root -p  
PasswordCHANGE  
MASTER TO MASTER_HOST='<master_server_ip>', MASTER_USER='<replication_user>',  
MASTER_PASSWORD='<password>', MASTER_LOG_FILE='<log_file>', MASTER_LOG_POS=<log_pos>;
```

```
mysql> SHOW MASTER STATUS;
+-----+-----+-----+-----+-----+
| File           | Position | Binlog_Do_DB | Binlog_Ignore_DB | Executed_Gt |
+-----+-----+-----+-----+-----+
| mysql-bin.000001 | 157      | mysqldb       |                    |              |
+-----+-----+-----+-----+-----+
```

d. Restart the MySQL service on the target server.

e. Log in to the MySQL server on the target server and execute the following command to set up replication:

```
CHANGE MASTER TO MASTER_HOST='[source_server_ip]', MASTER_USER='[replication_user]',
MASTER_PASSWORD='[replication_password]', MASTER_LOG_FILE='[log_file_name]', MASTER_LOG_POS=[log_position];
```

Replace [source\_server\_ip] with the IP address of the source server, [replication\_user] and [replication\_password] with the MySQL replication user credentials, and [log\_file\_name] and [log\_position] with the details from the source server's binary log.

f. Start the replication on the target server with the following command:

```
START SLAVE;
```

g. Verify that replication is working by checking the replication status on the target server:

```
SHOW SLAVE STATUS\G
```

Ensure that the Slave\_IO\_Running and Slave\_SQL\_Running values are both set to Yes.

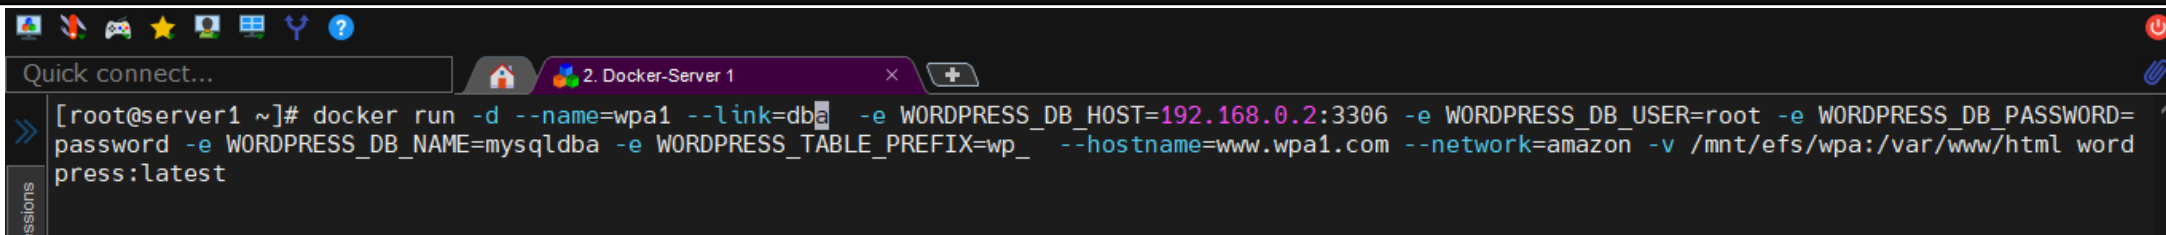

```
# docker restart dba
```

```
# docker exec -it dba /bin/bash
```

```
Mysql> cat /etc/my.cnf
```

- **Create WP Container (On server1 & 2 with attaching dba) & do same with dbb and there wp containers on both server1 & 2**

```
# docker run -d --name=wpa1 --link=dba -e WORDPRESS_DB_HOST=192.168.0.2:3306 -e  
WORDPRESS_DB_USER=root -e WORDPRESS_DB_PASSWORD=password -e  
WORDPRESS_DB_NAME=mysqldba -e WORDPRESS_TABLE_PREFIX=wp_  
--hostname=www.wpa1.com --network=amazon -v /mnt/efs/wpa:/var/www/html wordpress:latest  
# docker run -d --name=wpa2 --link=dba -e WORDPRESS_DB_HOST=192.168.0.2:3306 -e  
WORDPRESS_DB_USER=root -e WORDPRESS_DB_PASSWORD=password -e  
WORDPRESS_DB_NAME=mysqldba -e WORDPRESS_TABLE_PREFIX=wp_  
--hostname=www.wpa2.com --network=amazon -v /mnt/efs/wpa:/var/www/html wordpress:latest
```

A screenshot of a terminal window titled "2. Docker-Server 1". The terminal shows the execution of a Docker command to create a WordPress container named "wpa1". The command includes various options for linking to a database, setting environment variables for database host, user, password, and name, and mounting a volume for the WordPress content. The command is: `[root@server1 ~]# docker run -d --name=wpa1 --link=dba -e WORDPRESS_DB_HOST=192.168.0.2:3306 -e WORDPRESS_DB_USER=root -e WORDPRESS_DB_PASSWORD=password -e WORDPRESS_DB_NAME=mysqldba -e WORDPRESS_TABLE_PREFIX=wp_ --hostname=www.wpa1.com --network=amazon -v /mnt/efs/wpa:/var/www/html wordpress:latest`

**For wordpress content we will use shared EFS attached volume folders for both servers**

- **Create Network Load Balancer (NLB) and attach Target IP over wp containers**

```
# docker run -d --name=nlba -v /mnt/efs/nlba:/usr/local/etc/haproxy -p 4000:80 --network=amazon -u root  
haproxy  
# docker run -d --name=nlbb -v /mnt/efs/nlbb:/usr/local/etc/haproxy -p 4001:80 --network=azure -u root  
haproxy
```

```
# vi haproxy.cfg
#vim /haproxy/haproxy.cfg

global
    daemon
    maxconn 1024
    pidfile /var/run/haproxy.pid
    user root
    group root

defaults
    balance roundrobin
    timeout client 60s
    timeout connect 60s
    timeout server 60s

frontend haproxy_server
    bind *:80
    default_backend web_server

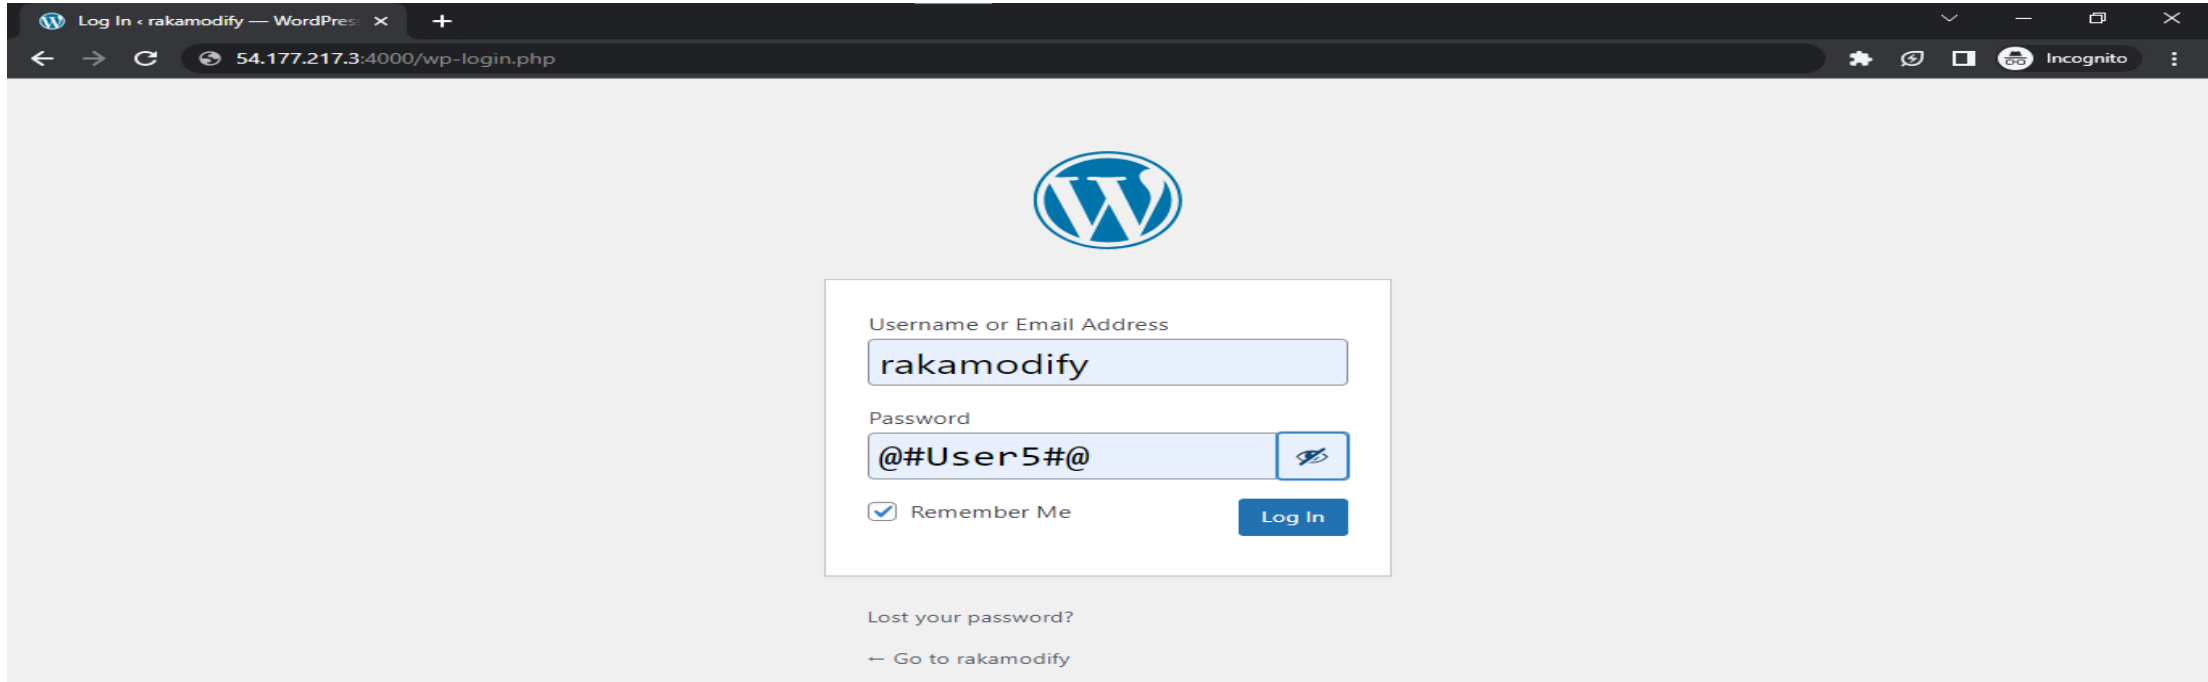

backend web_server
    balance roundrobin
    server server1 $web1_container_ip:80
    server server2 $web2_container_ip:80

---imp note for this file-----
find web1 and web2 container ip from docker
```

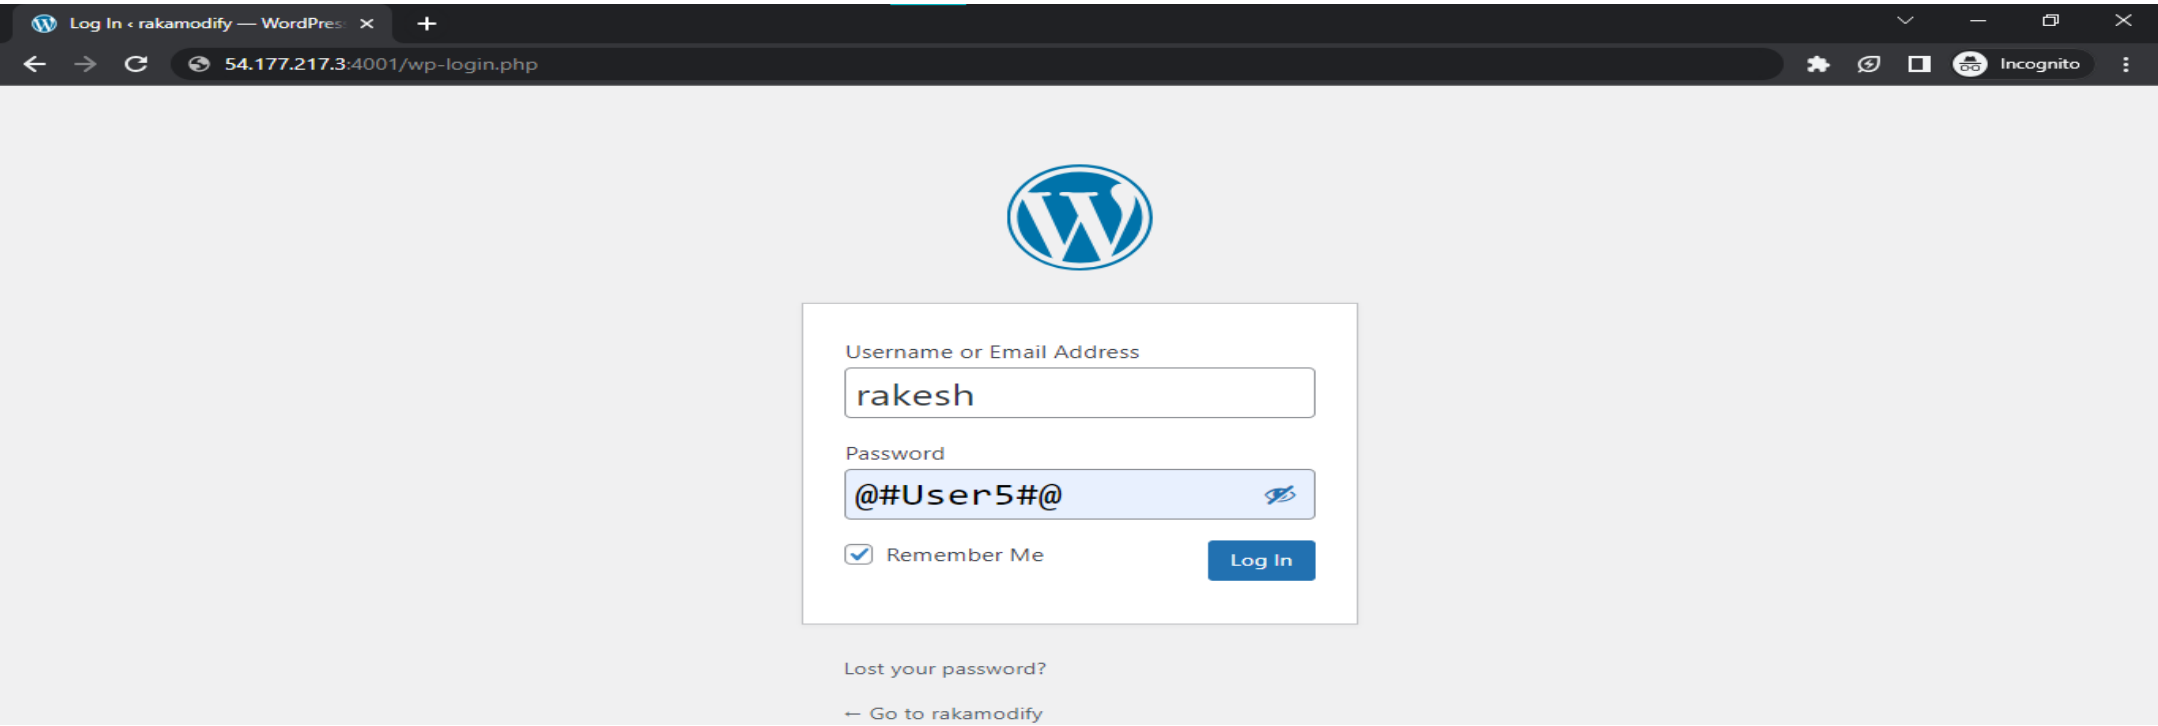

then replace the \$web1\_container\_IP from its actual ip of wpa1 & wpb1  
and replace the \$web2\_container\_IP from its actual ip of wpa1 & wpb1  
---imp note end -----

## ➤ Create Application Load Balancer and Configurations over attaching NLB

```
# docker run -d --name=alb1 -p 80:80 -v /mnt/efs/alb1:/etc/nginx/ --network=amazon nginx:latest
# vi nginx.conf
# cp ./nginx.conf /mnt/efs/alb1/
# cat /mnt/efs/alb1/nginx.conf
# docker exec -it alb1 /bin/bash
```

```
events {
    worker_connections 1024;
}
http {
    upstream app1_backend {
        server 192.168.0.5:80; # NLB1 IP and port
    }
    upstream app2_backend {
        server 12.168.0.5:80; # NLB1 IP and port
    }
    server {
        listen 80;
        server_name your_domain.com; # Replace with your actual domain name
        location /app1 {
            proxy_pass http://app1_backend;
            proxy_set_header Host $host;
            proxy_set_header X-Real-IP $remote_addr;
            # Additional proxy settings if needed
        }
    }
}
```

```
}
location /app2 {
    proxy_pass http://app2_backend;
    proxy_set_header Host $host;
    proxy_set_header X-Real-IP $remote_addr;
    # Additional proxy settings if needed
}
# Additional server configurations if needed
}
```

### Listeners and routing [Info](#)

A listener is a process that checks for connection requests using the port and protocol you configure. The rules that you define for a listener determine how the load balancer routes requests to its registered targets.

EC2

EC2 > Load balancers > Create Network Load Balancer

Create Network Load Balancer Info

The Network Load Balancer distributes incoming TCP and UDP traffic across multiple targets such as Amazon EC2 instances, microservices, and containers. When the load balancer receives a connection request, it selects a target based on the protocol and port that are specified in the listener configuration, and the routing rule specified as the default action.

How Elastic Load Balancing works

Basic configuration

Load balancer name

Name must be unique within your AWS account and can't be changed after the load balancer is created.

top-level-nlb

A maximum of 32 alphanumeric characters including hyphens are allowed, but the name must not begin or end with a hyphen.

Scheme

Scheme can't be changed after the load balancer is created.

Internet-facing

An internet-facing load balancer routes requests from clients over the internet to targets. Requires a public subnet. Learn more

Create Network Load Balancer

i

Suggested next steps

- Review, customize, or configure attributes for your load balancer and listeners using the **Description** and **Listeners** tabs within [top-level-nlb](#).
- Discover other services that you can integrate with your load balancer. Visit the **Integrated services** tab within [top-level-nlb](#).

View load balancer
